

## Hybrid Rockets

### Liquefying Solids – Enhanced Regression

## Hybrids – Increasing Regression Rate

- Options

Increased heat transfer to solid surface

More responsive material

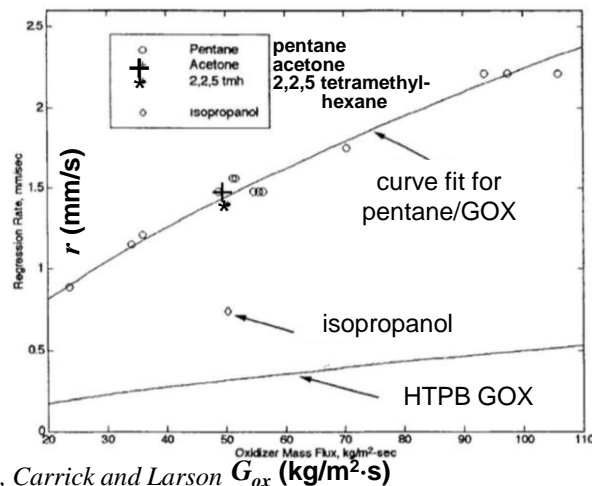

Method	Basic Idea	Drawbacks
Add oxidizers or exothermic decomposing mat'ls.	Increase heat transfer by moving flame towards surface	<ul style="list-style-type: none"> <li>Reduced safety</li> <li>Increased p dependence</li> </ul>
Add metal particles (micron sized)	Increase radiative heat transfer	<ul style="list-style-type: none"> <li>Small improvement</li> </ul>
Add metal particles (nano sized)	Move flame closer to surface and increase rad. heat transfer	<ul style="list-style-type: none"> <li>High cost</li> <li>Complex processing</li> </ul>
Swirl injection for liquid	Increased mass flux near surface	<ul style="list-style-type: none"> <li>Increased complexity</li> <li>Large motor scaling</li> </ul>
Solid with low $\Delta H_{\text{evap}}$	Lower heat transfer needed	<ul style="list-style-type: none"> <li>Limited options</li> <li>Increased blowing</li> </ul>

## Cyrogenic Solid Hybrids

- Work at AFRL (Edwards) in the early-mid 1990's to examine "frozen" solids
- Motivation
  - more flexibility on propellant selection ( $H_2$ ,  $O_2$ , ...) and possibility of adding metals to otherwise liquid propellants
  - retain nonexplosive, safe-handling features of the liquid propellants
- Worked on frozen organics (e.g., pentane) and GOx

## Example AFRL Results

- Regression rate 3-5  $\times$  faster than "standard" (HTPB-GOx)
- Opens possibility of reduced burning area ( $A_b$ ) for same thrust
  - single port
  - simpler manufacturing
  - higher volumetric efficiency
  - reduced sliver losses

AIAA-95-2948, Carrick and Larson  $G_{ox}$  (kg/m<sup>2</sup>·s)

## “New” Mechanism for Regression

- Classical model (Marxman, 1965)
  - vaporization of solid due to heat feedback from flame (usually diffusion limited)
- Modification
  - melting surface layer
  - formation of droplets that are entrained into gaseous flow

$$\dot{r} = \dot{r}_{evap} + \dot{r}_{entrainment}$$

after Cantwell AA 283, Ch. 11

**AE6450 Rocket Propulsion**

## Entrainment Mass Transfer

- Part of energy going to surface melts solid without vaporizing it
- Loss of mass from surface (thin film) due to entrainment given by

$$\dot{m}_{ent} \propto \frac{(\rho_g u_\infty^2)^\alpha (\Delta x)^\beta}{\sigma^\pi \mu_l^\gamma}$$

gas flow momentum flux  $(\rho_g u_\infty^2)^\alpha$  melt layer thickness  $(\Delta x)^\beta$

liquid surface tension  $\sigma^\pi$  liquid viscosity  $\mu_l^\gamma$

$\alpha \sim 1-1.5$   
 $\beta \sim 1-2$   
 $\pi \sim O(1)$   
 $\gamma \sim O(1)$

 and Gater and L'Ecuyer, *Intl J Heat Mass Trans* **13** (1970)

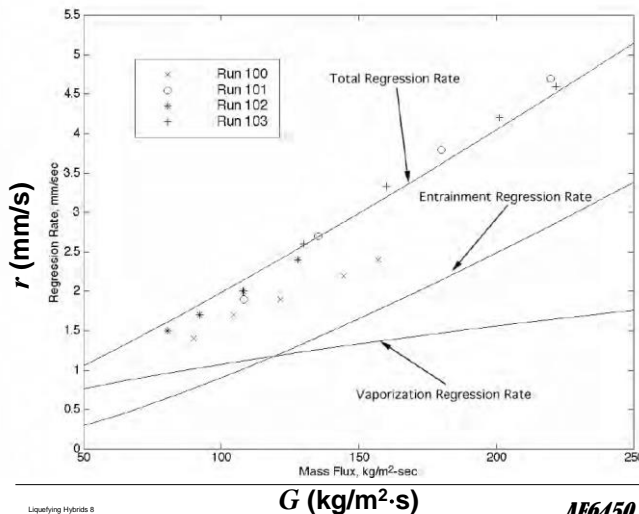

**AE6450 Rocket Propulsion**

## Other Changes to Hybrid Combustion Theory

- To include liquid layer effects
  - include reduced heating requirement to remove mass
  - reduce “blocking/blowing” effect (some of mass is initially denser, less of a pressure gradient produced)
  - increased surface roughness increases convective heat transfer coefficient to surface

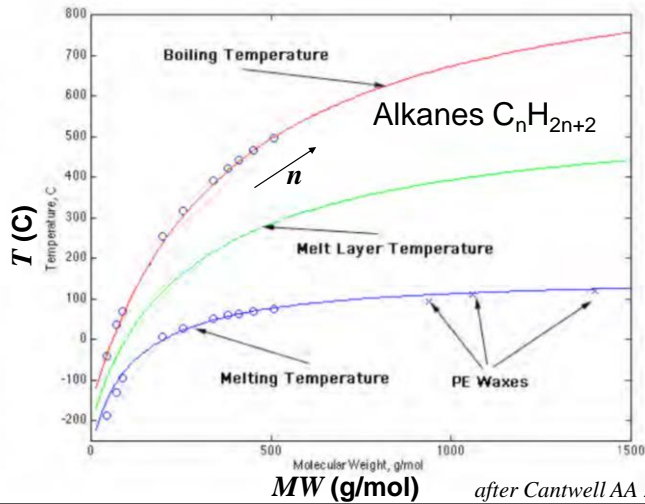

## Example Results

- Pentane-GOX predictions and data comparison

*Karabeyoglu, Altman and Cantwell, J Prop Power 18 (2002)*

## Comparison to Other Approaches

- To increase regression rate, the other major approach is adding metal particles to standard propellants (e.g., HTPB + oxidizer)
- In comparison, liquefying (paraffinic) fuels exhibit
  - significantly greater increase in regression rate
  - reduced efficiency and lower density specific impulse
  - reduced stiffness (without support structure)
- Optimum tradeoff depends on application specifics
