

## Liquid Propellant Storage

- Already described storage for gaseous propellants
- What about liquids like hydrazine?
- Issues
  - pressurization method
  - preventing gas from entering storage tank outlet

## Typical Thruster Pressurization Options

1. Externally stored inert gas pressurization, **regulated**
  - constant tank pressure
2. Internally stored inert gas pressurization, **blowdown**
  - tank pressure drops
  - larger tank for same liquid mass
3. **Vaporized** propellant
  - only for volatile propellants
  - pressure limited to  $p_{vap}$
4. **Piston** driven
  - less common

## Ullage Bubbles

- With simple tanks difficult to guarantee liquid wets outlet
  - in gravity field, vehicle orientation can change
  - in zero-g, ullage bubbles can float or wetting can inhibit liquid
- If (inert) gas enters thruster, thrust and pressurization gas lost
- How to prevent?

*Ullage ≡ tank volume not occupied by liquid*

## Positive Expulsion Methods

Fig. 5.47. Positive-Expulsion Devices to Manage Propellant. A physical barrier between the propellant and pressurant gas ensures that the gas is not inadvertently ingested.

- Mechanically separate pressurization gas and liquid propellant

## Positive Expulsion Methods

- Other advantages of positive expulsion
  - prevent pressurizing gas from dissolving in propellant
  - allows hot, reactive pressurizing gas (e.g., gas generator)

## Surface Tension Devices

- Use capillary attraction to maintain liquid at tank outlet
- Typically made of fine mesh, stainless steel wire screens near tank outlet

Fig. 5.49. Designs of Passive-Expulsion Devices Hold and Flow Configurations under Various Acceleration Conditions. In all cases, liquid "holds" near the outlet.  
from Humble, Henry and Larson, *Space Propulsion Analysis and Design* (1995)

- used alone, work best in low acceleration applications (surface tension vs. inertial forces)
